Association Between Blood Glucose Level and Outcomes in Patients Hospitalized for Acute Exacerbation of Chronic Obstructive Pulmonary Disease

Yusuf Kasirye, MD; Melissa Simpson, PhD; Chaitanya Kumar Mamillapalli, MD; Narendranath Epperla, MD; Hong Liang, PhD; Steven H. Yale, MD

ABSTRACT

Background: Increased blood glucose is associated with adverse clinical outcomes among patients with major illnesses. This study examined the association between blood glucose and adverse outcomes among hospitalized patients with acute exacerbation of chronic obstructive pulmonary disease, for which limited prior data were available.

Methods: We studied a cohort of 209 hospitalized patients with acute exacerbation of chronic obstructive pulmonary disease. Univariate analyses and multivariate logistic regression analyses with backward elimination method were performed to evaluate factors associated with in-hospital complications, length of hospitalization, 30-day hospital readmission, and 90-day all-cause mortality.

Results: Multivariate logistic regression analysis with backward elimination method revealed that lower blood glucose and age at hospital admission were the most significant risk factors for in-hospital complication. Received respiratory support and in-hospital complications were the most significant risk factors for the length of hospitalization. There were no significant risk factors associated with 30-day hospital readmission and 90-day all-cause mortality.

Conclusion: The analyses failed to reveal significant associations between higher blood glucose levels and adverse outcomes. We showed that lower glucose levels (hypoglycemia) results in higher risk for in-hospital complications. In-hospital complications results in longer length of hospitalization, which implies that lower glucose levels (hypoglycemia) indirectly may result in longer length of hospitalization. More studies are needed to better clarify the cause for these associations.

INTRODUCTION

Chronic obstructive pulmonary disease (COPD) is a condition affecting 24 million people and is the fourth leading cause of death in the United States, with inhospital mortality ranging from 2% to 30%. Identification of prognostic factors may lead to improved treatment strategies and clinical outcomes for COPD. Among acute exacerbation of COPD (AECOPD) patients, adverse outcomes are associated with lower arterial pH, older age, male gender, underlying comorbidities, higher income, disease severity, and in-hospital complications.

One readily available prognostic indicator is blood glucose. Data show that higher blood glucose is associated with adverse outcomes among patients with acute myocardial infarction, brain injury, community-acquired pneumonia, severe trauma, critical illness, and those undergoing cardiothoracic surgery. These results, along with the fact that nearly half of patients hospitalized with AECOPD suffer from hyperglycemia during hospitalization, suggest that blood glucose could serve as an important tool for patient monitoring during AECOPD hospitalization. Studies have shown that hospitalized COPD patients with elevated blood glucose have longer hospital stays, more frequent isolation of gram negative bacteria, late non-invasive ventilatory failure, and higher mortality risk.

The association between hyperglycemia and AECOPD outcomes has not been fully described. Baker et al reported a 15% increase in absolute risk of adverse outcomes for each 1 mol/l increase in blood glucose; however, the case definition used created the potential for inclusion of patients with conditions in
addition to AECOPD, such as bronchial asthma and pneumonia. Also, the authors’ limited analysis to the highest value occurring at any time during the hospitalization allows inference to be drawn from the absolute peak blood glucose value, but not from a complete picture of blood glucose during hospitalization.

The purpose of this study was to explore the association between blood glucose levels and clinical outcomes among hospitalized AECOPD patients on a general medical floor. We hypothesized that abnormal blood glucose (hypoglycemia and hyperglycemia) would be associated with adverse clinical outcomes.

**METHODS**

**Study Population**

A retrospective cohort of 209 patients hospitalized with a diagnosis of AECOPD within the Marshfield Epidemiology Surveillance Area (MESA), a 24-ZIP code area in central and northwestern Wisconsin, were identified. Following institutional review board approval (with waiver of informed consent), patients were validated manually as meeting the study’s inclusion criteria. Details about MESA are published elsewhere, but briefly, this cohort consists of about 85,000 residents who receive health care at Marshfield Clinic and its affiliates. Patients had been admitted to the largest 2 hospitals in the MESA catchment area with a diagnosis of AECOPD from January 1, 2004 to December 31, 2008. Each patient was identified using ICD-9 Code 491.21 and a prehospitalization diagnosis of COPD based on the Global Initiative for Chronic Obstructive Lung Disease (GOLD) criteria, which included (1) age 40–80 years; (2) history of smoking (>20 pack-years); (3) clinical history of COPD as measured at any time by an FEV$_1$/FVC (FEV$_1$ = forced expiratory volume in the first second of expiration/FVC = forced vital capacity) ratio <70% and FEV$_1$ <50% predicted. Inclusion criteria also included admission and discharge diagnosis of AECOPD and at least 2 blood glucose measurements during hospitalization. We excluded patients who were transferred from other facilities or those who were transferred to palliative or intensive care units within 24 hours of admission, newly diagnosed with lung cancer or pneumonia during the hospitalization, known to be HIV positive prior to admission, and those who left against medical advice. For patients with multiple admissions, the first admission was used. Data were obtained through electronic interrogation of the MESA database and manual chart abstraction.

**Data Collection**

Demographic and clinical data collected for all subjects included age, gender, spirometry results, arterial blood gas on admission, body mass index (BMI), smoking history, comorbid conditions (identified in the Charlson Comorbidity Index), use of noninvasive ventilation, plasma and serum blood glucose levels throughout the hospitalization, corticosteroid use with total daily dose (intravenous or oral), management of hyperglycemia (eg, diet, oral agents, insulin), and hospital discharge for reasons other than AECOPD within 30 days after the index hospital admission date.

Medical complications were extracted manually by review of patients’ discharge summaries, and were defined as health care-associated infections (bacteremia, pneumonia, systemic inflammatory response syndrome), neurological (delirium, cerebrovascular accidents, coma), cardiac (new onset atrial fibrillation, decompenated congestive heart failure, myocardial infarction), or renal (acute renal failure defined as a rise in serum creatinine of at least 0.5 mg/dL over 24 hours). Serum glucose measurements (capillary and serum) measured during hospitalization were obtained (Table 1). For each patient, a daily mean blood glucose value was calculated from all measurements (fasting and random) done during hospitalization. Random blood glucose measurements were taken using a portable glucometer; fasting blood glucose was measured by Siemens Chemistry analyzer (Dimesions Xpand and Dimension EXL200 models) using a spectrophotometric hexokinase method. Daily mean blood glucose was expressed in milligrams per deciliter (mg/dL).

**Statistical Analysis**

Univariate analyses and multivariate logistic regression analyses with backward elimination method were used to evaluate the effects of blood glucose on length of hospitalization (LOH),
complications, 30-day hospital readmission, and 90 days all-cause mortality. The other variables considered in multivariate logistic regression models were age, diabetes mellitus (DM) status, sex, steroid use 24 hours before hospitalization, current or past smoker, BMI, inhaled medications at time of presentation, history of chronic steroid use, number of blood glucose measurements taken per day, and respiratory support (invasive and non-invasive ventilation) received during hospitalization.

LOH was considered as a discrete outcome (ie, ≤3 days vs >3 days). In-hospital complication was considered as a categorical variable comparing those patients who had at least 1 complication during the index hospitalization to those who did not, while blood glucose was classified 2 ways: as a discrete variable (at least 1 daily mean <90 mg/dl vs others) and a discrete variable (at least 1 daily mean >140 mg/dl vs others). All analyses were performed using SAS version 9.2 (SAS Institute Inc., Cary, North Carolina).

RESULTS

In-hospital Complications

Twenty-four patients had in-hospital complications (Table 2). Univariate analysis revealed that lower blood glucose (at least 1 daily mean <90 mg/dl vs others) was significantly associated with in-hospital complication by comparing 37.5% of at least 1 daily mean <90 mg/dl at complication group with 9.2% at non-complication group, *P*=0.0003, and OR (95% CI vain 5.93 (2.26-15.57). Higher blood glucose (at least 1 daily mean >140 mg/dl vs others) was not significantly associated with in-hospital complication by comparing 75.0% of at least 1 daily mean >140 mg/dl at complication group with 82.2% at non-complication group, *P*=0.40, and OR (95%CI vain 0.65(0.24-1.77) (Table 3). Multivariate logistic regression analysis with backward elimination method revealed that the lower blood glucose and age at hospital admission were the most significant risk factors for in-hospital complications, where OR (95% CI vain 6.45(2.12-19.66) for the lower blood glucose, and 1.08 (1.01-1.15) for age.

Length of Hospitalization

Univariate analysis revealed that lower blood glucose was significantly associated with LOH by comparing 20.7% of at least 1 daily mean <90 mg/dl at hospitalization >3 days group with 9.3% at hospitalization ≤3 days group, *P*=0.03, and OR (95% CI vain 2.55 (1.10-5.92). Higher blood glucose was not significantly associated with LOH by comparing 87.9% of at least 1 daily mean >140 mg/dl at hospitalization >3 days group with 78.8% at hospitalization ≤3 days group, *P*=0.13, and OR (95% CI vain 1.95(0.81-4.73) (Table 4). Multivariate logistic regression analysis with backward elimination method revealed that respiratory support and in-hospital complication were the most significant risk factors for LOH, where OR (95% CI vain 4.68 (1.88-11.67) for respiratory support, and 3.74 (1.45-9.67) for in-hospital complication.

Hospital Readmission Within 30 Days

Thirty-six people were readmitted within 30 days of discharge from index hospitalization. Univariate analysis did not identify any factor associated with 30-day readmission, where OR (95% CI vain 1.96 (0.75-5.07) and *P*-value vain 0.17 for the lower blood glucose, as well as 1.18 (0.45-3.06) and *P*-value vain 0.74 for the higher blood glucose. Multivariate logistic regression analysis with backward elimination method failed to reveal any significant risk factor associated with 30-day hospital readmission. (Data not shown.)

Ninety Day All-cause Mortality

Eight people died due to any cause within 90 days of index hospitalization. Similarly, univariate analysis did not show any factor associated with 90-day all-cause mortality, where OR (95% CI vain 1.01(0.12-8.52) and *P*-value vain 0.99 for the lower blood glucose, as well as 0.36 (0.08-1.59) and *P*-value vain 0.18 for the higher blood glucose. Multivariate logistic regression analysis with backward elimination method did not reveal any significant risk factor either associated with 90-day hospital readmission. (Data not shown.)

DISCUSSION

Our study among hospitalized AECOPD patients on the general medical floor failed to reveal significant relationship between higher blood glucose and adverse clinical outcomes.

Our study differs from the study by Baker et al,18 which may explain the difference in results. First, our study population was defined based on prior spirometric measurements and World Health Organization (WHO) criteria for exacerbation, whereas the Baker study relied solely on ICD-10 codes. Second, the Baker study did not utilize any radiological data to rule out other pulmonary comorbidities, like pneumonia, which might confers a confounding effect on the data. Third, there were differences in methods for reporting blood glucose data. Studies utilized either a single admission blood glucose,5-11 daily mean blood glucose,14,15 or a single blood glucose obtained (fasting or nonfasting) during
The presence of hypoglycemia itself may be a marker for severity of illness, may have direct consequences itself, or be a treatment related side-effect. The presence of hypoglycemia, independent of treatment-related effects, may reflect defects in glucose counter-regulation, an imbalance between reduction in circulating insulin and enhanced glucagon secretion in response to lower glucose levels, or aberrant physiologic response to falling glucose levels. Therefore, the patient’s inability to mount a hyperglycemic response in the presence of these 2 biochemical processes might portend an adverse clinical outcome. Our study is the first to demonstrate that hypoglycemia as defined by a blood sugar less than 90 mg/dl in patients with AECOPD is associated with adverse clinical outcomes.

This study was performed in a rural, white population, which limits its generalizability to other populations.

roids in the treatment of COPD exacerbations has long been established, but we were unable to collect data regarding corticosteroid dosage, which is highly variable in clinical practice. Corticosteroid dosage likely exerts great influence on blood glucose trends, but the clinical importance of these fluctuations remains unclear. Although we looked at patients with spirometry, baseline disease severity per WHO/GOLD criteria staging was not included in our analysis. Also, it is important to note that although our study is large compared to previous studies, it is possible that it was not large enough to have the power necessary to detect the significant relationship between higher blood sugars and adverse outcomes in this population. Therefore, further larger studies in this population to incorporate this data would help to elucidate the complex interactions between metabolic control of blood glucose, extraneous hyperglycemic agents, and clinical outcomes.

CONCLUSION

Our study differed from previous studies by the absence of studies that examined the relationship between adverse outcomes and increased blood glucose levels. Interestingly, we found that blood sugars less than 90 mg/dL were associated with in-hospital complication and may indirectly result in longer LOH. Further studies examining dose and duration of steroid dose, as well as stratification based on spiro metric data, may provide further insights of the many subtleties and complexities of this association on LOH and adverse medical complications.

EDUCATIONAL OBJECTIVES

Upon completion of this activity, participants will be able to:

1. Appreciate the factors associated with adverse clinical outcomes in patients hospitalized with an acute exacerbation of chronic obstructive pulmonary disease (AECOPD).
2. Recognize the role that an altered blood glucose level may have on hospitalized patients with AECOPD and other acute illnesses.

PUBLICATION DATE: December 16, 2013

QUESTIONS

1. Chronic obstructive pulmonary disease is a chronic condition affecting 50 million people and is the sixth leading cause of death in the United States, with in-hospital mortality ranging from 2% to 30%.
   - True
   - False

2. Adverse outcomes of AECOPD are associated with:
   - Lower arterial pH, older age, female gender
   - Underlying comorbidities, disease severity, in-hospital complications
   - None of the above

3. Data from other studies have shown that higher blood glucose is associated with adverse outcomes among patients with acute myocardial infarction, brain injury, community-acquired pneumonia, severe trauma, critical illness, and those undergoing cardiothoracic surgery.
   - True
   - False

4. Hospitalized COPD patients with elevated blood glucose have been found in other studies to have longer hospital stays, more frequent isolation of gram negative bacteria, ventilatory failure, and a higher mortality risk.
   - True
   - False

5. The present study revealed a significant relationship between higher blood glucose levels and adverse clinical outcomes among patients hospitalized with AECOPD.
   - True
   - False

6. The present study revealed that among patients hospitalized with AECOPD, a lower blood glucose level was a significant risk factor associated with an in-hospital complication and increased hospital length of stay.
   - True
   - False

7. In the present study of patients with AECOPD, hospital readmission within 30 days and 90-day all cause mortality were significantly increased in patients with both increased and decreased blood sugar levels during hospitalization.
   - True
   - False
